Expoziční scénář Verze č. 1 - EN Strana 1 (celkem 39)

The Chemical Safety Report (CSR) for copper sulphate pentahydrate lists downstream uses that have been identified by ourselves Each of these identified uses have been examined and sub-divided into a series of pre-defined processes resulting in workplace exposure (PROC codes) and environmental exposure (ERC codes). For each of these processes, standard assessment tools have been used to identify practices (including operating conditions and risk management measures) under which copper sulphate pentahydrate may "safely" be used at sites with standardized characteristics.

No attempt has been made in the CSR to further define the potential for overall exposure that may be associated with an identified use at a "real" site. Instead downstream users are invited to adapt the available exposure data to their own site-specific circumstances (with appropriate "scaling" of available data, if necessary) and develop their own safe emission scenarios.

In view of the highly complex nature of the CSR, generic information applicable to development of the eSDS has been extracted and presented in this document for clarity. This information comprises:

- Tabulated lists of identified uses, broken down to show processes that may lead to exposure of industrial workers, professional workers and the environment (as point sources and/or wide dispersive uses, as applicable).
- "Safe" use scenarios that have been determined for each PROC and ERC code under a variety of standardized circumstances, including relevant operating conditions and risk management measures.

In utilizing this information downstream users should review the detailed scenarios that have been developed for the PROC and ERC codes applicable to their uses of interest. Information on operating conditions and risk management measures that is applicable to the specific circumstances of their downstream uses can then be extracted and used to build up tailored safe-use scenarios.

# 1. PROC and ERC Codes Associated with Identified Uses

PROC and ERC codes associated with different Identified Uses are summarized in the following tables for Industrial workers and Professional workers. Information relating to Consumer use of products and articles is also presented (this is also applicable to workers who use these items).

# spERC codes for both industrial and professional uses of copper compounds

In addition to the ERC codes, separate spERCs are available (developed by ARCHE consultants) for 'Metal compound formulation' [spERC F] and 'Industrial use of Metal compounds [spERC U]. These can be applied to downstream use processes that comply with the relevant on-site conditions.

<u>spERC F</u>: This spERC is considered appropriate for both open and closed systems using both wet and dry processes and is based on information gathered for metal compounds used in formulation activities. The activities listed include mixing and blending of metal compounds into preparations in the following formulating industries: catalysts, glass, pigments, paints, coatings, plastics, rubber stabilisers and water treatment chemicals (note, however, that the spERC may also be applied to other formulating industries, provided they meet the criteria discussed below). The spERC has been developed by considering how the existing appropriate RMMs can be used to achieve the necessary reduction in emissions. For air emissions, the spERC value was based on the finding that RMMs for air present in >80% of the sites included:

- Electrostatic precipitation;
- Fabric or bag filters (most common);
- Ceramic filters;
- Wet scrubbers (most common);
- Dry or semi-dry scrubbers.

From the available data, the maximum 90<sup>th</sup> percentile reported site-specific release factor to air (after RMM) from the formulation processes investigated was 0.004%.

For the releases to waste water the spERC value was based on the RMMs for water present in >60% of the sites including:

- Chemical precipitation;
- Sedimentation;
- Filtration;
- Electrolysis (rare).

The 50<sup>th</sup> percentile of the reported site-specific removal efficiency for 18 sites was 94% (50.00% - 93.30%). The maximum emission of the 90<sup>th</sup> percentiles of reported site-specific release factors to waste water was given as 0.5%. This is a worst-case assumption as waste water RMMs were confirmed at >60% site, suggesting that the 90<sup>th</sup> percentile release factor did not include RMMs. Therefore, an additional on-site removal step via an on-site WWTP may be added to the exposure scenario.

Emissions to soil were not considered to be relevant to metal compound formulation as the activities are undertaken largely indoors.

<u>spERC U</u>: This spERC is considered appropriate for both open and closed systems using both wet and dry processes and is based on information gathered for the use of metal compounds in the following industrial sectors: crystal manufac- ture, leather tanning, pigments, paints, coatings, plastics, rubber and textiles (note, however, that the spERC may also be applied to other sectors, provided they meet the criteria discussed below). The spERC has been developed by consider- ing how the existing appropriate RMMs can be used to achieve the necessary reduction in emissions. For air emissions, the spERC value was based on the findings that the RMMs for air present in >50% of the sites included: Expoziční scénář Verze č. 1 - EN Strana 9 (celkem 39)

- Electrostatic precipitation;
- Fabric or bag filters (most common);
- Ceramic filters;
- Wet scrubbers (most common);
- Dry or semi-dry scrubbers.

From the available data the maximum 90<sup>th</sup> percentile reported site-specific release factor to air (after RMM) from the activities investigated was 0.1%.

For the releases to waste water the spERC value was based on the RMMs for water present in >50% of the sites including:

- Chemical precipitation;
- Sedimentation;
- Filtration;
- Electrolysis.

The 50<sup>th</sup> percentile of the reported site-specific removal efficiency for 12 sites was 95% (50.00% – 99.95%). The maximum emission of the 90<sup>th</sup> percentiles of reported site-specific release factors to waste water was given as 0.6% (after on-site RMM).

While site specific scaling with additional RMMs will be possible for individual sites, insufficient information is currently available for any further amendment of the generic spERC scenario.

The exposure resulting from the generic scenarios is presented below.

# 2. Exposure Scenarios Determined for Each PROC and ERC Code

All downstream use exposure scenario predictions are based on the standard EUSES 2.0 model for the environment and MEASE for worker exposure, in line with the available guidance for REACH.

The downstream uses of copper sulphate are considered in terms of user (industrial, professional, consumer) and environmental exposure route (point source and wide dispersive emissions). The range of copper sulphate uses is very diverse and, in order to provide assessments that can be applied as flexibly as possible, all potential worker activities (expressed in terms of PROC codes) and routes of environmental exposure (expressed as ERCs and spERCs) have been evaluated. These are treated as individual generic exposure scenarios (GES). In all cases, human and environmental exposure is expressed in terms of <u>copper</u>. Worker exposure scenarios also distinguish between the use of copper compounds in either liquid (assumed to be a solid at room temperature dissolved in water to produce an aqueous solution or slurry) or solid form. Solid forms are further classified as having low, medium or high dustiness, as defined by the developers of MEASE using the Rotating Drum Method (RDM);

- <u>1.</u> <u>Solid, low dustiness</u>: Granules, pellets, wetted powders, etc. with little potential for dust emissions (dustiness is less than 2.5% according to the RDM).
- 2. <u>Solid, medium dustiness</u>: powders and dust consisting of relatively coarse particles with moderate potential to become (and stay) airborne (dustiness is less than 10% RDM).

Expoziční scénář Verze č. 1 - EN Strana 10 (celkem 39)

3. <u>Solid, high dustiness</u>: fine powders having high potential to become and stay airborne.

The RMD methodology is defined within the European Committee for Standardization (CEN/TC137/WG3) 2006 document providing standardisation in measurement of dustiness of bulk powders (EN15051<sup>1</sup>). This standard establishes two reference test methods (single drop or rotating drum method) that classify dustiness in terms of health-related fractions of bulk solid materials.

The resulting scenarios, including information on associated operating conditions and risk management measures, are summarized in the tables that follow. In order to clearly identify each GES for downstream use of copper sulphate, the following descriptor codes have been developed: Environmental GES all have the prefix **E-GES**; worker GES all have the prefix **W-GES** (industrial) or **PW-GES** (professional) and consumer GES have the prefix **C-GES**. All of these then have '**DU**' for downstream use or '**WDU**' for widespread downstream use, as applicable. In order to define the specific release category or activities investigated within individual GES, a number of additional sub-categories have been added:

Scenario			Description
E-GES-DU	Tier	1	Tier 1 – defaults from ERC codes
		2	Tier 2 – spERC <sup>†</sup> /measured data
	Waste water treat-	0	No waste water emission
	ment Environmental	1	Waste water treated once at STP*
	re- lease category	(2)	Formulation of mixtures
	(ERC)	(3)	Formulation in materials
		(4)	Industrial use of processing aids in processes and prod-
			ucts, not becoming part of articles
		(5)	Industrial use resulting in inclusion into or onto a matrix
		(6a)	Industrial use resulting in manufacture of another sub-
			stance (use of intermediates)
		(6b)	Industrial use of reactive processing aids
		(6d)	Industrial use of process regulators for polymerisation
			processes in production of resins, rubbers, polymers
		(7)	Industrial use of substances in closed systems
		(12a)	Industrial processing of articles with abrasive techniques
			(low releases)
		(spERC F)	Industrial formulation of metal compounds
		(spERC U)	Industrial use of metal compounds
E-GES-WDU	Environmental re-	(ERC8a-c)	Wide dispersive indoor use of substance
	lease category (ERC)	(ERC8d-f)	Wide dispersive outdoor use of substance
		(ERC9a)	Wide dispersive indoor use of substance in closed sys- tems
		(ERC9b)	Wide dispersive outdoor use of substance in closed sys- tems
		(ERC10a)	Wide dispersive outdoor use of long-life articles with low release
		(ERC10b)	Wide dispersive outdoor use of long-life articles with high or intended release
		(ERC11a)	Wide dispersive indoor use of long-life articles with low release
		(ERC11b)	Wide dispersive indoor use of long-life articles with high or intended release
W/PW-GES-DU	Substance form	(High)	Solid, high dustiness
		(Med)	Solid, medium dustiness
		(Low)	Solid, low dustiness

<sup>1</sup> European Committee for Standardization. EN 15051. Workplace atmospheres - Measurement of the dustiness of bulk materials - Requirements and reference test methods, 2006.

Scenario		Description	
	(Liquid)	Liquid, aqueous solution or slurry	
C-GES-DU	Various unspecified articles and product	3	

<sup>†</sup> In addition to the ERC codes, spERCs have been developed to assess exposure from downstream formulation and use. These are applicable to open and closed systems using wet and dry processes and are based on specific RMM information gathered for metal compounds in various indusindus- trial activities. spERCs may be applied in preference to the default ERCs for sites that are known to comply with the stipulated conditions. \* On-site WWTP can be introduced where applicable; Use of a sewage treatment plant (STP) presents a worst-case approach, as this allows for an assessment of risk to STP microorganisms, and the impact of sludge disposal to land.

### 3. eSDS Examples

The following eSDS examples present the environmental and worker exposure for industrial, professional and consumer uses of copper sulphate as defined by the generic approach adopted within the CSR submitted in 2010. These are <u>ONLY</u> intended to serve as an example and require further amendment by suppliers/downstream users in the development of specific eSDS documentation.

All text in italics is guidance provided by the ECHA [Guidance on information requirements and chemical safety assessment: Exposure scenario format – in part D: Exposure scenario building; in part F: CSR format. Source: <u>http://guidance.echa.europa.eu/docs/guidance\_document/information\_requirements\_ESformat\_en.pdf</u>] or refer to text that the 'Supplier/DU' may need to note/amend/remove in order to adopt the same format for their own substance/product specific eSDS.

### **Generic Exposure - Industrial Setting**

Exposure Scenario – Exposure resul	ting from industrial uses								
1. Title GES – Industrial downstream us									
Life cycle	Use (industrial) stage of copper sulphate								
Free short title	Generic downstream industrial use of copper sulphate								
Systematic title based on use descriptor	List of all use descriptors related to the life cycle stage and all the uses under it; include market sector (by PC), if relevant; SU: SU3 – Industrial use <u>PROC</u> : 1, 2, 3, 4, 5, 7, 8a, 8b, 9, 10, 13, 14, 15, 17, 22, 23, 24, 25 [identified] PC: Various/not applicable								
	AC: Not applicable <u>ERC</u> : 2, 3, 4, 5, 6a, 6b, 6d, 7, 8a*, 8c-e*, 10a*, 11a* [identified; *Wide dispersive use] <u>spERC</u> : F, U [where applicable]								
Processes, tasks, activities covered	Downstream use of Copper sulphate								
(workers)	All possible processes, tasks and activities described by the selected PROCs								
Further explanations (if needed)         Copper sulphate is widely used within downstream industrial processes, which are covered within this generic exposure scenario.         Specific details of each industrial process must be added here by the individual DU.									
2. Exposure scenario									
2.1 Contributing scenario (1) Controlling environmental exposure for <u>all industrial DU</u> of Copper sulphate [E-GES- DU1.0/2.0/1.1[ERC/spERC]/2.1[ERC/spERC]]									
Environmental related free short title	Generic exposure of the environment from the industrial DU of Copper sulphate								

Predicted (modelled) local and regional (measured) concentrations of copper are used for calculation of the PEC – Tools available: EUSES 2.0 / Suitable scaling tools

## Product characteristics

**Assessment Method** 

Purity: To be added by Supplier/DU

<u>Form</u>: Solid (High, medium and low dustiness) or liquid (aqueous solution)

See Section 2.1.1: GENERIC Exposure: All forms have been investigated where applicable.

# Frequency and duration of use

# To be added by Supplier/DU:

Intermittent (used < 12 times per year for not more than 24 h) <u>or</u> continuous use/release

See Section 2.1.1: GENERIC Exposure: Continuous production is assumed as a worst case. It is possible that use is not continuous; this has to be considered when estimating exposure.

### Environment factors not influenced by risk management

To be added by Supplier/DU: [only where releases to waste water occurs as a result of use]

Flow rate of receiving waters

Dilution factor of 10, based on flow rate of receiving surface water (m3/d, a default of 18,000 m3/d is assumed for a standard EU town. please note: the default flow rate will be rarely changeable for downstream uses).

See Section 2.1.1: GENERIC Exposure: Default for generic scenario: 18,000 m3/d, unless specified otherwise.

### Other given operational conditions affecting environmental exposure

### To be added by Supplier/DU:

Other given operational conditions: e.g. technology or process techniques determining the initial release of substance from process (via air and waste water); dry or water based processes; conditions related to temperature and pressure; indoor or outdoor use of products; work in confined area or open air, e.g.;

- In the wet process, most of the operations are in wet phase.
- In the direct and indirect dry process, all operational conditions are dry throughout the process; there are no process waters; high temperature steps;
- Even when no process waters (e.g. when dry process throughout), some non-process water can be generated containing zinc (e.g. from cleaning)
- All processes are performed indoor in a confined area. All residues containing zinc are recycled.

See Section 2.1.1: GENERIC Exposure: no operational conditions specified all wastewater emissions are based on ERC/spERC data. Technical conditions and measures at process level (source) to prevent release

<u>To be added by Supplier/DU:</u> Process design aiming to prevent releases and hence exposure to the environment; this includes in particular conditions ensuring rigorous containment; performance of the containment to be specified (e.g. by quantification of a release factors in section 2.1.1 below), e.g.;

- Process enclosures and closed circuits where relevant and possible.
- Dust capturing and removal techniques are applied on local exhaust ventilation on furnaces and other work areas with potential dust generation.
- Containment of liquid volumes in sumps to collect/prevent accidental spillage

See Section 2.1.1: GENERIC Exposure: no operational conditions specified all wastewater emissions are based on ERC/spERC data. Technical onsite conditions and measures to reduce or limit discharges, air emissions and releases to soil

Expoziční scénář Verze č. 1 - EN Strana 13 (celkem 39)

<u>To be added by Supplier/DU:</u> Technical measures, e.g. on-site waste water and waste treatment techniques, scrubbers, filters and other technical measures aiming at reducing releases to air, sewage system, surface water or soil; this includes strictly controlled conditions (procedural and control technology) to minimise emissions; specify effectiveness of measures; specify the size of industrial sewage treatment plant (m3/d), degradation effectiveness and sludge treatment (if applicable);

- On-site waste water treatment techniques can be applied to prevent releases to water (if applicable) e.g. chemical precipitation, sedimentation and filtration (efficiency **90-99.98**%).
- Air emissions are controlled by use of bag-house filters and/or other air emission abatement devices
   e.g. fabric (or bag) filters (up to 99% efficiency), wet scrubbers (50-99% efficiency). This may create a general negative pressure in the building.

### See Section 2.1.1: GENERIC Exposure assumptions:

Air: 0.4% emission assumed irrespective of ERC.

This value is taken from the worst-case available metal spERCs (Use of metals and metal compounds in metallic coating v1.1 Arche consultancy). This approach has been adopted due to negligible volatility of copper. The default ERC values for air emissions are unreasonably high.

Waste water : Either;

- No release to water, or

- Release as dictated by appropriate ERC or spERC (see Section 2.1.1 for specific % releases).

**Soil:** No significant direct releases assumed. However, where a municipal STP is used emissions via sewage sludge need to be taken into account.

<u>Wide dispersive use</u>: In relation to releases to water, the scenario for both indoor and outdoor wide dispersive uses is based on the assumption that they occur in the urban infrastructure, are collected in a central public sewage system and are then treated by an STP. For outdoor uses, this scenario can be considered a reasonable worst case. To assume that all releases occur on a paved surface of an urban infrastructure and are collected in a sewage system may be considered overly conservative, but this is balanced by the assumption that all releases to water are treated in an STP. Direct releases to air and soil are not considered in the wide dispersive use scenario.

### Organisational measures to prevent /limit release from site

0

<u>To be added by Supplier/DU:</u> Specific organisational measures or measures needed to support the functioning of particular technical measures. Those measures need to be reported in particular for demonstrating strictly controlled conditions. *i.e.* 

- In general emissions are controlled and prevented by implementing an integrated management system e.g. ISO 9000, ISO 1400X series, or alike, and, when applicable, by being IPPC-compliant.
  - Such management system should include general industrial hygiene practice e.g.:
    - information and training of workers,
    - regular cleaning of equipment and floors,
    - procedures for process control and maintenance,
- Treatment and monitoring of releases to outside air, and exhaust gas streams (process & hygiene), according to national regulation.
- SEVESO 2 compliance, if applicable

See Section 2.1.1: GENERIC Exposure: no operational conditions specified all wastewater emissions are based on ERC/spERC data.

### Conditions and measures related to municipal sewage treatment plant

<u>To be added by Supplier/DU:</u> Size of municipal sewage system/treatment plant (m3/d); specify degradation effectiveness; sludge treatment technique (disposal or recovery); measures to limit air emissions from sewage treatment (if applicable); please note: the default size of the municipal STP (2000 m3/d) will be rarely changeable for downstream uses.

See Section 2.1.1: GENERIC Exposure assumptions: In cases where applicable: the default size has been used.

Conditions and measures related to external treatment of waste for disposal

Expoziční scénář Verze č. 1 - EN Strana 14 (celkem 39)

<u>To be added by Supplier/DU:</u> Fraction of used amount transferred to external waste treatment for disposal; type of suitable treatment for waste generated by workers uses, e.g. hazardous waste incineration, chemical-physical treatment for emulsions, chemical oxidation of aqueous waste; specify effectiveness of treatment;

- If any, all hazardous wastes are treated by certified contractors according to EU and national legislation.
- Users of Cu-compounds have to favour the recycling channels of the end-of-life products
- Users of Cu-compounds have to minimize Cu-containing waste, promote recycling routes and, for the remaining, dispose the waste streams according the Waste regulation.

See Section 2.1.1: GENERIC Exposure assumptions: no additional emissions to the environment via solid waste have been included in the assessment as disposal via appropriate waste streams have been assumed.

### Conditions and measures related to external recovery of waste

<u>To be added by Supplier/DU:</u> Fraction of used amount transferred to external waste treatment for recovery: specify type of suitable recovery operations for waste generated by workers uses, e.g. re-distillation of solvents, refinery process for lubricant waste, recovery of slags, heat recovery out-side waste incinerators; specify effectiveness of measure;

• All residues are recycled or handled and conveyed according to waste legislation.

See Section 2.1.1: GENERIC Exposure assumptions: no additional emissions to the environment via solid waste have been included in the assessment as disposal via appropriate waste streams have been assumed.

### Amounts used

<u>Fo be added by Supplier/DU</u> : Daily and annual amount per site (for uses in industrial setting) <u>or </u> daily and annual amount f	or wide
disperse uses	

See Section 2.1.1 for generic guidance on allowable use of 'copper' within copper sulphate: Amounts released in waste water <u>should not</u> result in environmental concentrations for each compartment that exceeds the established effect threshold value given in section 2.1.1. Information on associated default emissions to air and water is provided, based on specified default assumptions for RMM and the assumed characteristics of the receiving environment.

2.1.1Generic guidance – ERC/spERC related: Technical conditions and measures to control emissions to the environment resulting from <u>all industrial DU</u> of Copper sulphate [E-GES-DU1.0/2.0; E-GES-DU1.1[ERC]; E-GES-WDU[ERC]; E-GES-DU2.1[spERC]]

Effects and background data Effect threshold data [predicted no effect concentration (PNEC) data in the relevant environmental compartments cannot exceed these levels]

ceed these levels]

Maximum off-site copper emission via water

Using the above information regarding emission factors and controls, the maximum off-site copper emission has been calculated to be either:

- 1. 0.8575 kg Cu/d assuming connection to a municipal STP and receiving water with a default flow rate of 18000 m<sup>3</sup>/d (dilution factor of 10), or
- 0.6174 kg Cu/d assuming direct release to receiving water [following on-site treatment] with a default flow rate of 18000 m<sup>3</sup>/d (dilution factor of 10).

These values are intended to be illustrative. DU should confirm that they can support the environmental releases from their processes with the necessary monitoring and scaling calculations.

2.1.1.2 Wide dispersive use assessment

E-GES-WDU1.1

Emissions covered: Tier 1 (ERC codes) - wide dispersive uses

It has not been possible to derive maximum allowable emissions for individual wide dispersive uses of copper sulphate. However, measured region-specific PEC data available for STP effluents from 3 EU countries (Belgium, the Netherlands and UK) range between 0.011 and 0.054 mg total Cu/l. The highest PEC of 0.054 mg total Cu/l, reported in the UK, was shown to be equivalent to 0.008 mg dissolved Cu/l.

These data suggest that emissions to receiving water courses with dilutions  $\geq 10 \leq 15$  would be sufficient to remove any concern for the aquatic environment as a result of wide dispersive uses of products containing Copper sulphate. This approach and these data have been presented and accepted within the VRA (2008) for the consideration of all copper inputs across the EU.

For individual assessments the default release data are available below.

3. Guidance to DU to evaluate whether he works inside the boundaries set by the ES

**Environment:** 

### Scaling tool: Metals EUSES IT tool (free download: http://www.arche-consulting.be/Metal-CSA-toolbox/du-scaling-tool).

Scaling of the release to air and water environment includes: Refining of the release factor to air and waste water and/or the efficiency of the air filter and waste water treatment facility.

It should be noted that the maximum allowable emissions to wastewater presented in this document have been modelled on the basis of standardised (default) assumptions regarding the efficiency of municipal sewage treatment plants (where present) and dilution/flow rate of receiving waters. These standardised assumptions may not accurately reflect the conditions that prevail at a particular site. As such, the information presented in this document should be regarded as a guidance tool only. It remains the responsibility of the user to ensure that a compound is used safely within the context of their site and in full consultation with the relevant local authorities.

Workers – Industrial:

Scaling tool: MEASE - Occupational Exposure Assessment Tool for REACH (free download: http://www.ebrc.de/ebrc/ebrc-mease.php).

Scaling considering duration and frequency of use: Collect process occupational exposure monitoring data. It should be noted that the evaluation of worker safety presented in this document is based on standardised (default) assump-

tions on levels of exposure associated with generic processes, the behaviour of a compound in a particular working environment and the presumed efficiency of Risk Management Measures (e.g. LEV; RPE). These standardised assumptions may not accurately reflect the conditions that prevail within a specific workplace. As such, the information presented in this document should be regarded as a guidance tool only. It remains the responsibility of the user to ensure that a compound is used safely within the context of their site and in full consultation with the relevant local authorities.

Predictions for inhalation exposure in the workplace may be further refined using the modelling approach set out in the copper Risk Assessment Report (2008), Chapter 4.1.2, Human Health Effects.

containing zinc (e.g. j		
	formed indoor in a confined area. All residues containing zinc are recycled.	
ee Section 2.1.1: GENERIC Exposure: n	o operational conditions specified all wastewater emissions are based on ERC/spERC	
ata.		

<u>To be added by Supplier/DU:</u> Process design aiming to prevent releases and hence exposure to the environment; this includes in particular conditions ensuring rigorous containment; performance of the containment to be specified (e.g. by quantification of a release factors in section 2.1.1 below), e.g.;

- Process enclosures and closed circuits where relevant and possible.
  - Dust capturing and removal techniques are applied on local exhaust ventilation on furnaces and other work areas with potential dust generation.
  - Containment of liquid volumes in sumps to collect/prevent accidental spillage

See Section 2.1.1: GENERIC Exposure: no operational conditions specified all wastewater emissions are based on ERC/spERC data.

### Technical onsite conditions and measures to reduce or limit discharges, air emissions and releases to soil

<u>To be added by Supplier/DU:</u> Technical measures, e.g. on-site waste water and waste treatment techniques, scrubbers, filters and other technical measures aiming at reducing releases to air, sewage system, surface water or soil; this includes strictly controlled conditions (procedural and control technology) to minimise emissions; specify effectiveness of measures; specify the size of industrial sewage treatment plant (m3/d), degradation effectiveness and sludge treatment (if applicable);

- On-site waste water treatment techniques can be applied to prevent releases to water (if applicable) e.g. chemical precipitation, sedimentation and filtration (efficiency **90-99.98**%).
- Air emissions are controlled by use of bag-house filters and/or other air emission abatement devices e.g. fabric (or bag) filters (up to 99% efficiency), wet scrubbers (**50-99**% efficiency). This may create a general negative pressure in the building.

### See Section 2.1.1: GENERIC Exposure assumptions:

Air: 0.4% emission assumed irrespective of ERC.

This value is taken from the worst-case available metal spERCs (Use of metals and metal compounds in metallic coating v1.1 Arche consultancy). This approach has been adopted due to negligible volatility of copper. The default ERC values for air emissions are unreasonably high.

Waste water : Either;

- No release to water, or

- Release as dictated by appropriate ERC or spERC (see Section 2.1.1 for specific % releases).

**Soil:** No significant direct releases assumed. However, where a municipal STP is used emissions via sewage sludge need to be taken into account.

<u>Wide dispersive use</u>: In relation to releases to water, the scenario for both indoor and outdoor wide dispersive uses is based on the assumption that they occur in the urban infrastructure, are collected in a central public sewage system and are then treated by an STP. For outdoor uses, this scenario can be considered a reasonable worst case. To assume that all releases occur on a paved surface of an urban infrastructure and are collected in a sewage system may be considered overly conservative, but this is balanced by the assumption that all releases to water are treated in an STP. Direct releases to air and soil are not considered in the wide dispersive use scenario.

Organisational measures to prevent /limit release from site

To be added by Supplier/DU: Specific organisational measures or measures needed to support the functioning of particular

technical measures. Those measures need to be reported in particular for demonstrating strictly controlled conditions. i.e.

- In general emissions are controlled and prevented by implementing an integrated management system e.g. ISO 9000, ISO 1400X series, or alike, and, when applicable, by being IPPC-compliant.
  - Such management system should include general industrial hygiene practice e.g.:
    - information and training of workers,
    - regular cleaning of equipment and floors,
    - procedures for process control and maintenance,
- Treatment and monitoring of releases to outside air, and exhaust gas streams (process & hygiene), according to national regulation.
- SEVESO 2 compliance, if applicable

See Section 2.1.1: GENERIC Exposure: no operational conditions specified all wastewater emissions are based on ERC/spERC data.

Expoziční scénář Verze č. 1 - EN Strana 25 (celkem 39)

### Conditions and measures related to municipal sewage treatment plant

<u>To be added by Supplier/DU:</u> Size of municipal sewage system/treatment plant (m3/d); specify degradation effectiveness; sludge treatment technique (disposal or recovery); measures to limit air emissions from sewage treatment (if applicable); please note: the default size of the municipal STP (2000 m3/d) will be rarely changeable for downstream uses.

See Section 2.1.1: GENERIC Exposure assumptions: In cases where applicable: the default size has been used.

### Conditions and measures related to external treatment of waste for disposal

<u>To be added by DU:</u> Fraction of used amount transferred to external waste treatment for disposal; type of suitable treatment for waste generated by workers uses, e.g. hazardous waste incineration, chemical-physical treatment for emulsions, chemical oxidation of aqueous waste; specify effectiveness of treatment;

- If any, all hazardous wastes are treated by certified contractors according to EU and national legislation.
- Users of Cu-compounds have to favour the recycling channels of the end-of-life products
- Users of Cu-compounds have to minimize Cu-containing waste, promote recycling routes and, for the remaining, dispose the waste streams according the Waste regulation.

See Section 2.1.1: GENERIC Exposure assumptions: no additional emissions to the environment via solid waste have been included in the assessment as disposal via appropriate waste streams have been assumed.

### Conditions and measures related to external recovery of waste

<u>To be added by Supplier/DU:</u> Fraction of used amount transferred to external waste treatment for recovery: specify type of suitable recovery operations for waste generated by workers uses, e.g. re-distillation of solvents, refinery process for lubricant waste, recovery of slags, heat recovery out-side waste incinerators; specify effectiveness of measure;

• All residues are recycled or handled and conveyed according to waste legislation.

See Section 2.1.1: GENERIC Exposure assumptions: no additional emissions to the environment via solid waste have been included in the assessment as disposal via appropriate waste streams have been assumed.

### Amounts used

<u>To be added by Supplier/DU</u>: Daily and annual amount per site (for uses in industrial setting) <u>or</u> daily and annual amount for wide disperse uses

See Section 2.1.1 for generic guidance on allowable use of 'copper' within copper sulphate: Amounts released in waste water <u>should not</u> result in environmental concentrations for each compartment that exceeds the established effect threshold value given in section 2.1.1. Information on associated default emissions to air and water is provided, based on specified default assumptions for RMM and the assumed characteristics of the receiving environment.

Maximum off-site copper emission via water	1

Using the above information regarding emission factors and controls, the maximum off-site copper emission has been calculated to be either;

- 1. 0.8575 kg Cu/d assuming connection to a municipal STP and receiving water with a default flow rate of 18000  $m^3/d$  (dilution factor of 10).
- 2. 0.6174 kg Cu/d assuming direct release to receiving water [following on-site treatment] with a default flow rate of 18000 m<sup>3</sup>/d (dilution factor of 10).

<u>These examples are intended to be illustrative</u>. DU should confirm that they can support the environmental releases from their processes with the necessary monitoring and scaling calculations.

2.1.1.2 Wide dispersive use assessment

E-GES-WDU1.1

Emissions covered: Tier 1 (ERC codes) – wide dispersive uses

It has not been possible to derive maximum allowable emissions for individual wide dispersive uses of copper sulphate. However, measured region-specific PEC data available for STP effluents from 3 EU countries (Belgium, the Netherlands and UK) range between 0.011 and 0.054 mg total Cu/l. The highest PEC for the STP of 0.054 mg total Cu/l, reported in the UK, was shown to be equivalent to 0.008 mg dissolved Cu/l.

These data suggest that emissions to receiving water courses with dilutions  $\geq 10 \leq 15$  would be sufficient to remove any concern for the aquatic environment as a result of wide dispersive uses of products containing Copper sulphate. This approach and these data have been presented and accepted within the VRA (2008) for the consideration of all copper inputs across the EU.

For individual assessments the default release data are available below.

### Maximum off-site copper emission via water

Using the above information regarding emission factors and controls, the maximum off-site copper emission has been calculated to be either;

- 0.8575 kg Cu/d assuming connection to a municipal STP and receiving water with a default flow rate of 18000 m<sup>3</sup>/d (dilution factor of 10), or
- 2. 0.6174 kg Cu/d assuming direct release to receiving water [following on-site treatment] with a default flow rate of 18000 m<sup>3</sup>/d (dilution factor of 10).

This is only intended as an example and DU should ensure that they check that they can support the environmental releases from their processes with the necessary monitoring and scaling calculations.

3. Guidance to DU to evaluate whether he wor	rks inside the boundarie	s set by the ES		

### Environment:

### Scaling tool: Metals EUSES IT tool (free download: http://www.arche-consulting.be/Metal-CSA-toolbox/du-scaling-tool).

Scaling of the release to air and water environment includes: Refining of the release factor to air and waste water and/or the efficiency of the air filter and waste water treatment facility.

It should be noted that the maximum allowable emissions to wastewater presented in this document have been modelled on the basis of standardised (default) assumptions regarding the efficiency of municipal sewage treatment plants (where present) and dilution/flow rate of receiving waters. These standardised assumptions may not accurately reflect the conditions that prevail at a particular site. As such, the information presented in this document should be regarded as a guidance tool only. It remains the responsibility of the user to ensure that a compound is used safely within the context of their site and in full consultation with the relevant local authorities.

### Workers - Professional:

# Scaling tool: MEASE - Occupational Exposure Assessment Tool for REACH (free download: http://www.ebrc.de/ebrc/ebrc-mease.php).

Scaling considering duration and frequency of use. Collect process occupational exposure monitoring data. It should be noted that the evaluation of worker safety presented in this document is based on standardised (default) assumptions on levels of exposure associated with generic processes, the behaviour of a compound in a particular working environment and the presumed efficiency of Risk Management Measures (e.g. LEV; RPE). These standardised assumptions may not accurately reflect the conditions that prevail within a specific workplace. As such, the information presented in this document should be regarded as a guidance tool only. It remains the responsibility of the user to ensure that a compound is used safely within the context of their site and in full consultation with the relevant local authorities.

Predictions for inhalation exposure in the workplace may be further refined using the modelling approach set out in the copper Risk Assessment Report (2008), Chapter 4.1.2, Human Health Effects.

### **Generic Exposure – Consumer**

The format related to consumers' uses should include conditions controlling consumers' exposure and environmental exposure. Note: the content of this exposure scenario is to be communicated to downstream users producing consumer products (mixtures).

Where the format is related to service life (and subsequent waste life stage) following from downstream uses, this should include conditions controlling consumers' and environmental exposure. Note: the content of this exposure scenario is to be communicated to the downstream users producing articles to be handled by consumers.

The measures controlling risks to consumers are predominantly to be addressed under product characteristics (first subheadline). Other measures might be considered as well, if deemed appropriate. However, **please note**: Information on hazards, behavioural advice and personal protection measures are usually not expected to be effective for reducing consumer exposure, unless the registrant has particular evidence available. For the risk management measures information on the required/assumed effectiveness has to be reported (if applicable and relevant). This is because the use of consumer instructions as RMMs cannot be expected to be highly effective, unless consumer behavioural data provide evidence that a sufficient degree of compliance can be assumed. Consumer RMMs based on instructions should be introduced only when the use of such RMMs can be shown to be effective and be well adhered to by consumers. Expoziční scénář Verze č. 1 - EN Strana 34 (celkem 39)

There are limited circumstances for consideration of personal protective equipment (PPE) in consumer exposure, because people will not necessarily use PPE even though recommended by the manufacturer. Even when PPE is provided with the product (e.g., gloves with a hair dye), it cannot be ensured that consumers will use it. The exposure estimation needs to consider the reasonable worst-case situation which indicates no use of gloves or other PPE. As an element of good practice and personal hygiene, the advice to use household gloves or other skin protection should be part of consumer instructions (e.g. for products that are irritating/corrosive to the skin, such as strongly acidic, alkaline or oxidising household detergents). [See: Chapter R.15 – Guidance on Consumer Exposure Estimation, Version 2 (April 2010). Source: <u>http://guidance.echa.europa.eu/docs/guidance\_document/information\_requirements\_r15\_en.pdf\_Note:</u> For consumer uses, section 4 contains information addressed to the formulator producing the consumer product, not the consumer. ]

The following format is for guidance only.

Exposure scenario – Addressing us	ses carried out by consumers
1. Title GES – Consumer downstream use	of Copper sulphate
Life cycle	Use stage of Copper sulphate
Free short title	Generic consumer use of Copper sulphate
Systematic title based on use descriptor	SU: Main PC: 1, 9a, 9b, 9c, 12, 15, 24, 30, 31, 35 AC: 2 ERC: 8a-f*, 9a*, 9b*, 10a*, 10b*, 11a*
Processes, tasks, activities covered (workers)	This scenario covers consumer end use of the following product types containing Copper sulphate :
2. Exposure scenario	
2.1 Contributing scenario (1) Controlling WDU[ERC]]	environmental exposure for all consumer DU of Copper sulphate [E-GES-

fecting exposure.	
Amounts used	
	supplied into the consumer use(s) covered in this exposure scenario.
Frequency and duration of use <u>To be added by Supplier</u> : Usually continue tions.	ous use/release (365 days) to be assumed, unless there are significant seasonal varia-
Environment factors not influenced by ri	sk management
	eiving surface water (m3/d) (usually 18,000 m3/d by default for the standard town);
· · · · <del></del> · · ·	

### please note: the default flow rate will be rarely changeable for downstream uses.

### Other given user conditions affecting environmental exposure

<u>To be added by Supplier</u>: Other operational conditions, e.g. indoor or outdoor use of products.

Conditions and measures related to municipal sewage treatment plant

Size of municipal sewage system/treatment plant (m3/d) (usually 2000 m3/d by default for the standard town); specify degradation effectiveness; sludge treatment technique (disposal or recovery); measures to limit air emissions from sewage treatment (if applicable; ) **please note**: the default size of the municipal STP will be rarely changeable for downstream uses.

### Conditions and measures related to external treatment of waste for disposal

Fraction of used amount transferred to external waste treatment for disposal: type of suitable treatment for waste generated by consumer uses, e.g. municipal waste incineration, hazardous waste incineration: specify efficacy of treatment; provide corresponding instructions regarding separation of waste to be communicated to consumers;

Conditions and measures related to external recovery of waste

Fraction of used amount transferred to external waste treatment for recovery: Specify type of suitable recovery operations for waste generated by consumer uses, e.g. refinery process for lubricant waste; specify efficacy of measure; provide corresponding instructions regarding separation of waste to be communicated to consumers

Use specific measures expected to reduce the predicted exposure beyond the level estimated based on the exposure scenario. 2.1.1Generic guidance – ERC/spERC related: Technical conditions and measures to control emissions to the environment resulting from <u>all consumer DU</u> of Copper sulphate [E-GES-WDU[ERC] only applicable]

E-GES-WDU1.1

Emissions covered: Tier 1 (ERC codes) – wide dispersive uses

It has not been possible to derive maximum allowable emissions for individual wide dispersive uses of copper sulphate. However, measured region-specific PEC data available for STP effluents from 3 EU countries (Belgium, the Netherlands and UK) that range between 0.011 and 0.054 mg total Cu/I. The highest PEC for the STP of 0.054 mg total Cu/I, reported in the UK, was shown to be equivalent to 0.008 mg dissolved Cu/I.

These data suggest that emissions to receiving water courses with dilutions  $\geq 10 \leq 15$  would be sufficient to remove any concern for the aquatic environment as a result of wide dispersive uses of products containing Copper sulphate. This approach and these data have been presented and accepted within the VRA (2008) for the consideration of all copper inputs across the EU.

For individual assessments the default release data are available below.

Environmental Release Code	ERC 8a
Life cycle stage (LCS)	Wide dispersive use
Type of use in LCS	Wide dispersive indoor use of processing aids in open systems
Default release to water from process [%]	100

Conditions and measures related to information and behavioural advice to consumers
To be added by Supplier/DU: Safety advice to be communicated to consumers in order to control exposure, e.g. technical in-
struction, behavioural advice; please note: usually such measures are not expected to be effective, unless the registrant has
available particular evidence that consumers follow the advice. These measures may however be included under the "Good
Practice Advice", and thus the effectiveness of the instructions/advice would not be taken into account when deriving exposure
estimates and risk characterisation in the CSR.
Conditions and measures related to personal protection and hygiene
<u>To be added by Supplier/DU</u> : Usually personal protection measures are not expected for consumer products; however if e.g.
gloves are recommend this can be specified here; specify the suitable material for the PPE (where relevant,) and advise how
long the protective equipment can be used before replacement (if relevant);please note: usually such measures are not ex-
pected to be effective if applied by consumers. Thus, is recommended to include these measures under the "Good Practice Ad-
vice", rather than taking the use of PPE into account when deriving exposure estimates and risk characterisation in the CSR.
Information from CSR:
To be added by Supplier/DU:
Consumer exposure scenario for combined occupational and consumer assessment:
The consumer exposure assessments are not directly relevant to workers. It is also assumed that workers in the cop-
per/Copper sulphate industries are unlikely to take copper in dietary supplements. Therefore, for the purpose of combining
occupational and consumer exposures for this group, a separate consumer scenario is considered following the Cu VRA. As a
typical consumer scenario for workers, it will be assumed that they are exposed via the dermal route to 0.14 mg Cu/day to
coins and to 4.3E <sup>-6</sup> mg Cu/day via hair-care products. As a RWC consumer scenario for workers, it will be assumed that work-
ers are exposed via the dermal route to 0.28 mg Cu/day to coins, to 1.4E <sup>-5</sup> mg Cu/day via hair-care products and via the inhala-
tion route to 0.001 mg Cu/person/day by smoking cigarettes.
Consumer exposure scenario:
The exposure estimation for consumer exposure only can be found below.
The most relevant routes of exposure are summarised below. Selection of the worst-case exposure route is based on con-
ine most relevant routes or exposure are summanised below. Selection of the worst-case exposure route is based on con-
sumer estimations from the Cu VRA (2008).
